Contrary to popular belief, Wisconsin receives enough sunshine to make passive solar design worth considering when building or remodeling.

Passive solar design uses a building's orientation, structure and materials to capture the sun's energy. Taking advantage of the sun is not a new idea. In Mesa Verde, Colorado, ancient cave dwellings were oriented to the south, using the cave overhang to protect the dwellings from direct summer sun, but receiving its warming rays in the winter. Homes in any climate can take advantage of solar energy by incorporating passive solar design features. Even in Wisconsin's cold winters, passive solar design can help cut heating costs and increase comfort.

HOW DOES IT WORK?

Passive solar design uses the sun's energy for heat, light and ventilation by using particular design strategies and materials rather than mechanical equipment. Such buildings are designed to absorb solar heat during winter days and contain it to provide warmth at night. Overhangs are used to block excessive heat gain during the summer. Natural convection currents can be employed to move air through the building for ventilation and heat distribution.

Passive solar design can be incorporated into an existing building, particularly where there is good orientation to the south. The addition of an attached greenhouse or sunspace, for example, offers a number of passive solar advantages. Air warmed by the sun can be blown into the house during the day, and a concrete or tile floor will soak up heat to provide some warmth at night. The space will also provide an extended growing season for vegetables and flowers!

To take best advantage of the possibilities of passive solar, however, these features should be part of the original building design. Two important aspects of a passive solar building—orientation and energy efficiency—are most successfully and economically addressed in new construction.

BENEFITS OF PASSIVE SOLAR ENERGY

Comfort. Because a well-designed passive solar home or building is highly energy efficient, it is

free of drafts. Extra sunlight from the south windows makes it more cheerful and pleasant in the winter than a conventional house.

Economy. Passive solar construction doesn't have to cost more than conventional construction, and it saves money on fuel bills. Extra money invested in high-quality windows and insulation usually offers a quick payback, and the building will require a smaller heating system in Wisconsin's cold climate.

Aesthetics. Passive solar buildings can have a conventional appearance on the outside, but the passive solar features make them light and pleasant inside.

Environmentally responsible. Passive solar homes can significantly cut use of heating fuel and electricity used for lighting. If passive cooling strategies are used in the design, summer air conditioning costs can be reduced as well.

Passive solar design in Wisconsin

IMPORTANT COMPONENTS

Siting

To soak up the winter sun, the building should be oriented with the longest wall facing within 15 degrees of true south. Living spaces should be placed on the south side to take advantage of natural heating and lighting. Place rooms with low heating, lighting and use requirements (e.g., storage and utility rooms) on the north side of the building.

Landscaping can be used to provide natural insulation. Evergreen trees can be planted on the north and west sides as a buffer against cold winter winds. The south side of the building should be kept clear of trees and shrubs that would block the sun. Even trees that lose their leaves can block over 30 percent of the available sunlight.

Building Envelope

In passive solar homes and buildings, energy efficiency should come first. The structure should be well-caulked, weather-stripped and insulated. Storm windows and movable window insulation can be used in the winter to help reduce heat

LARRY KROM

(above) The passive solar features designed into the Midwest Renewable Energy Association's headquarters in Custer, Wisconsin, would also work well for a residence. Shown here is the building's southern facade with its many windows. Note the clerestory windows at the top that bring solar energy into the rear of the building. Also, note the small skylights that admit abundant light during the day, but lose a minimum of heat at night. A house with passive solar features like these would not be out of place among conventionally designed houses.

(left) The movement of the sun through the seasons is well illustrated in this diagram. Correct placement of a home on a specific site is an important part of passive solar design.

loss. A home performance specialist can help identify cost effective measures.

Windows and Overhangs

In a passive solar building design, most of the windows are located on the south wall. Multi-pane glass with low-e coatings is recommended to maximize incoming heat while minimizing heat loss. Windows on the north wall should be small to reduce heat loss, and those located on the east and west might need shading from vegetation to reduce heat from morning or evening sun.

Exterior overhangs are required on the south side of the building to block direct summer sun. Ideal proportions for an overhang are calculated by latitude and have become established standards used by passive solar designers. The overhang needs to be enough to block summer sun, but not so much that it blocks the sun desired in the winter.

Thermal Mass

Thermal mass is material that soaks up heat when the sun is shining and then slowly radiates

Passive solar design in Wisconsin

that heat at night. Good examples of thermal mass are stone, brick, concrete and adobe brick. These materials are not good insulators. However, if they are located inside well-insulated outer walls (as flooring or inside partitions), the heat they collect during the day will be captured for nighttime distribution inside the structure. The amount of thermal mass inside the building must be balanced with the window area to ensure that the building is not too hot or too cold. Computer programs are available to calculate the proper amount of thermal mass needed, or a good passive solar designer can make the calculations.

OTHER CONSIDERATIONS

- Working with a good designer or architect is worth the investment. Solar home tours are

available and offer the opportunity to visit successful examples of passive solar design.

- Passive solar design works best in open floor plans that allow heat to flow throughout the home.
- A back-up heating system will be needed for Wisconsin winters and is also required to get a building permit.

Living in a passive solar home brings greater awareness of the seasons and the climate and requires some operation to mitigate the changes. For example, if summer ventilation has been incorporated it will be necessary to open and close vents as the seasons change. Also, it is advisable to use heavy drapes or window insulation at night during the coldest months to keep heat loss to a minimum.

Passive solar design takes advantage of the differing positions of the sun in summer and winter. This diagram shows how the winter sun can enter the windows and be soaked up by the thermal mass of walls and floors. In summer, overhangs at the windows keep the sun's heat out.
